

Math 356: Number Theory (Rutgers)

DAVID YANG

Winter Break, 2023

Abstract

These notes arise from lecture videos of Math 356: Number Theory (Quadratic Forms), originally taught by Professor [Alex Kontorovich](#), at Rutgers University. I am grateful to Professor Kontorovich for releasing the [lecture videos](#) online. I am responsible for all faults in this document, mathematical or otherwise; any merits of the material here should be credited to Professor Kontorovich and not to me. Feel free to message me with any suggestions or corrections at dyang5@swarthmore.edu.

1 Introduction to Fermat's Last Theorem

Theorem 1 (Fermat's Last Theorem, 1637)

There are no positive integers x, y, z that satisfy

$$x^n + y^n = z^n$$

for integer $n > 2$.

An equivalent formulation is the one discussed in lecture:

$$x^n + y^n = z^n$$

where $n > 2$ is an integer, has no non-trivial solutions x, y , and z in \mathbb{Q}, \mathbb{Z} .

Definition 2 (Diophantine Problem)

A **Diophantine problem** is a polynomial equation solved in \mathbb{Z} and \mathbb{Q} .

Fermat's Last Theorem is an example of a Diophantine problem.

Historically, in 1993, Andrew Wiles published a proof of Fermat's Last Theorem. Later, Wiles and his student Richard Taylor rectified the 1993 proof and published the first successful proof. For these efforts, Wiles won the 2016 Abel Prize and the 2017 Copley Medal.

With some extra background, we can prove Fermat's Last Theorem for $n = 4$.

1.1 Parameterization of Pythagorean Triples

Theorem 3 (Primitive Pythagorean Triple Generation)

If (x, y, z) is a **primitive** pythagorean triple^a ($\nexists d$ such that $d \mid x, d \mid y$ and $d \mid z$), then z is odd. Furthermore, assuming that x is odd and y is even, then there exists coprime $r, s \in \mathbb{Z}$ with such that

$$x = r^2 - s^2, y = 2rs, z = r^2 + s^2.$$

^aif (x, y, z) is a primitive Pythagorean triple, then it follows that x, y , and z are pairwise primitive.

Proof Sketch (Theorem 3). Since y is even, we can rewrite $y = 2y_1$ for some integer y_1 . Since (x, y, z) are a Pythagorean triple, it follows that $y^2 = z^2 - x^2 = (z - x)(z + x)$. Substituting and expanding, we get that

$$4y_1^2 = (z - x)(z + x).$$

Since x, z are both odd, we can rewrite $z - x = 2a$ and $z + x = 2b$, so

$$y_1^2 = ab$$

where $(a, b) = 1$. Consequently, a, b must themselves be perfect squares. We conclude that $y_1 = rs$, where $r^2 = a, s^2 = b$, and so it follows that $y = 2rs$ for coprime r, s . \square

1.2 Pythagorean Varieties

Definition 4 (Variety)

A **variety** is a set of solutions to a system of polynomial equations.

Consider the variety $\mathcal{V} : x^2 + y^2 - z^2$, which is a Pythagorean variety. Note that $\mathcal{V}(\mathbb{R})$ is a structure consisting of two cones which are reflections about the z -axis, and $\mathcal{V}(\mathbb{Z}), \mathcal{V}(\mathbb{Q})$ are subsets of $\mathcal{V}(\mathbb{R})$.

Lemma

For every $\vec{v} \in \mathcal{V}(\mathbb{Q})$, there exists a unique primitive $\vec{w} \in \mathcal{V}(\mathbb{Z})_+^0$ with $\vec{w} \sim \vec{v}$, where $\vec{u} \sim \vec{v} \iff \vec{u} = \lambda \vec{v}, \lambda \in \mathbb{R} \setminus \{0\}$.

Note that $\mathcal{V}(\mathbb{R})_+ / \sim$ can be thought of as S^1 ; for a point $(x, y, z) \in \mathcal{V}(\mathbb{R})_+ \mapsto (\frac{x}{z}, \frac{y}{z}, 1)$. Furthermore, $\mathcal{V}(\mathbb{R}) / \sim = S^1 \cup \{0\}$.

Furthermore, note that another set of representatives of $\mathcal{V}(\mathbb{Q})_+ / \sim$ is $S^1(\mathbb{Q})$. This gives a notion for why Pythagorean triples are fundamental: they parameterize rational points on the unit circle. Formally,

$$\left(\frac{r}{u}, \frac{t}{u}\right) \in S^1(\mathbb{Q}) \iff (r, t, u) \in \mathcal{V}(\mathbb{Z})_+^0$$

1.3 Proof of Fermat's Last Theorem for $n = 4$

Statement. $x^4 + y^4 = z^4$ in \mathbb{Z} implies $xyz = 0$.

Stronger Statement. $x^4 + y^4 = z^2$ in \mathbb{Z} implies $xyz = 0$.

Proof. Suppose there is a solution to $x^4 + y^4 = z^2$ in \mathbb{Z} with $xyz \neq 0$. Then (x^2, y^2, z) is a Pythagorean triple. Furthermore, since we can scale Pythagorean triples by their GCD to get a primitive triple, we can assume that $(x^2, y^2, z) \in \mathcal{V}(\mathbb{Z})_+^0$ is rather a primitive Pythagorean triple. By the Parameterization of primitive Pythagorean triples, there exists coprime $r, s \in \mathbb{Z}$ such that

$$x^2 = r^2 - s^2, y^2 = 2rs, z = r^2 + s^2.$$

Furthermore, since x^2 is odd and y^2 is even by assumption, r and s also have opposite parity. From the first equation, we know that

$$x^2 + s^2 = r^2,$$

where x is odd, forcing s to be even, and r to be odd. Once again, (x, s, r) is a primitive Pythagorean triple, so there exists coprime $u, v \in \mathbb{Z}$ such that

$$x = u^2 - v^2, s = 2uv, r = u^2 + v^2$$

where $(r, s) = 1$. We also know that $y^2 = 2rs$ from our first primitive Pythagorean triple (x^2, y^2, z) . Since y is even, we can express it as $y = 2y_1$ for some $y_1 \in \mathbb{Z}$. Since $r = u^2 + v^2, s = 2uv$, and $y = 2y_1$, we have that

$$4y_1^2 = 2(u^2 + v^2)(2uv)$$

and so

$$y_1^2 = uv(u^2 + v^2).$$

Note however that $(u, v) = 1$. Consequently, u , v , and $u^2 + v^2$ are three pairwise coprime numbers whose product is a perfect square. Thus, u , v , and $u^2 + v^2$ must themselves be a perfect square. We now write

$$u = a^2, v = b^2, u^2 + v^2 = c^2$$

From the third equation, we have that $a^4 + b^4 = c^2$.

Note that if $xyz \neq 0$, then

$$c \leq c^2 = u^2 + v^2 \leq (u^2 + v^2)^2 = r^2 < r^2 + s^2 = z.$$

Thus, we have found a smaller, in the sense that $c < z$, primitive solution to $x^4 + y^4 = z^2$ with $abc \neq 0$.

We can continue this process of finding primitive solutions until we arrive at a trivial solution. Thus, by the principle of infinite descent¹, we conclude that $x^4 + y^4 = z^2$ in \mathbb{Z} implies $xyz = 0$. \square

2 Modular Arithmetic

Note: Basic modular arithmetic notes skipped due to prior knowledge. Important theorems/results added for completeness.

Theorem 5 (Fermat's Little Theorem)

If p is a prime with $p \nmid a$,

$$a^{p-1} \equiv 1 \pmod{p}.$$

Proof. Note that $\{1 \cdot a, 2 \cdot a, \dots, (p-1) \cdot a, p \cdot a\}$ is a complete residue system modulo p . It follows that

$$(1 \cdot a)(2 \cdot a) \dots ((p-1) \cdot a) \equiv 1 \cdot 2 \cdot 3 \dots (p-1) \pmod{p}.$$

Simplifying, we have that

$$(p-1)!a^{p-1} \equiv (p-1) \pmod{p}.$$

Equivalently, we have that $p \mid (p-1)!(a^{p-1} - 1)$. Since $p \nmid (p-1)!$, it follows that $p \mid a^{p-1} - 1$, so

$$a^{p-1} \equiv 1 \pmod{p}. \quad \square$$

2.1 Linear Diophantine Equations

Let $S = \{an + bm \mid n, m \in \mathbb{Z}\} \dots$

Theorem 6

$S = d\mathbb{Z}$, where $d = \gcd(n, m)$.

Proof. First, note that $S \subseteq d\mathbb{Z}$. If $d \mid n$ and $d \mid m$, then $d \mid an$ and $d \mid bm$, so $d \mid an + bm$. It remains to show that $an + bm = d$ has a solution. It is possible to find such a solution by reversing the steps of the Euclidean Algorithm using n and m . \square
